

# **VisionLabs LUNA PLATFORM 5**

**Migration manual from 4.5.4 to v.5.67.0**

**v.5.67.0**

## Contents

<b>Default ports for services</b>	<b>5</b>
<b>Configuration names for services</b>	<b>6</b>
<b>Introduction</b>	<b>7</b>
<b>1 Before upgrade</b>	<b>8</b>
1.1 Accounts migration notes . . . . .	9
1.2 Backups creation . . . . .	9
1.3 Delete old symbolic link . . . . .	9
1.4 Distribution unpacking . . . . .	10
1.5 Symbolic link creation . . . . .	10
1.6 Changing group and owner for directories . . . . .	11
1.7 Move Image Store buckets . . . . .	11
1.8 SELinux and Firewall . . . . .	11
1.9 Create log directory for new services . . . . .	12
1.10 License update . . . . .	12
1.10.1 Actions from License activation manual . . . . .	12
1.11 Docker installation . . . . .	13
1.12 Calculations using GPU . . . . .	14
1.13 Login to registry . . . . .	14
1.14 Remove LUNA PLATFORM 4 containers . . . . .	15
<b>2 Services launch</b>	<b>16</b>
2.1 Third-party services . . . . .	17
2.1.1 InfluxDB . . . . .	17
2.1.2 PostgreSQL . . . . .	17
2.1.3 Redis . . . . .	18
2.2 Configurator . . . . .	20
2.2.1 Optional services usage . . . . .	20
2.2.2 Configurator DB recreation . . . . .	20
2.2.3 Configurator DB tables creation . . . . .	21
2.2.4 Run Configurator container . . . . .	22
2.3 Image Store . . . . .	23
2.3.1 Samples migrations . . . . .	23
2.3.2 Image Store container launch . . . . .	23
2.3.3 Buckets creation . . . . .	24
2.3.4 Add TTL for local-buckets . . . . .	26
2.3.5 Add TTL for S3 buckets . . . . .	26

2.4	Accounts . . . . .	28
2.4.1	Admin DB transformation . . . . .	28
2.4.2	Accounts DB tables creation . . . . .	28
2.4.3	Accounts container launch . . . . .	29
2.5	Licenses . . . . .	30
2.5.1	Specify license settings using Configurator . . . . .	30
2.5.2	Licenses container launch . . . . .	31
2.6	Faces . . . . .	32
2.6.1	Faces database migration . . . . .	32
2.6.2	Faces container launch . . . . .	32
2.6.3	Add VLMatch function to Faces database . . . . .	32
2.7	Events . . . . .	34
2.7.1	Events database migration . . . . .	34
2.7.2	Events container launch . . . . .	34
2.7.3	Add VLMatch function to Events database . . . . .	34
2.8	Python Matcher services . . . . .	36
2.8.1	Use Python Matcher without Python Matcher Proxy . . . . .	36
2.8.2	Python Matcher container launch . . . . .	36
2.9	Remote SDK . . . . .	37
2.9.1	Remote SDK container launch . . . . .	37
2.10	Handlers . . . . .	42
2.10.1	Change the used database for Handlers . . . . .	42
2.10.2	Handlers database migration . . . . .	42
2.10.3	Handlers container launch . . . . .	42
2.11	Tasks . . . . .	44
2.11.1	Tasks database migration . . . . .	44
2.11.2	Tasks and Tasks Worker containers launch . . . . .	44
2.12	Sender . . . . .	46
2.12.1	Sender container launch . . . . .	46
2.13	API . . . . .	47
2.13.1	API container launch . . . . .	47
2.13.2	Account creation . . . . .	47
2.14	Admin . . . . .	49
2.14.1	Admin container launch . . . . .	49
2.15	Backport 4 . . . . .	50
2.15.1	Backport 4 container launch . . . . .	50
2.15.2	User Interface 4 . . . . .	51

<b>3</b>	<b>Additional information</b>	<b>52</b>
3.1	Monitoring and logs visualization using Grafana	53
3.1.1	LUNA Dashboards	53
3.1.2	Grafana Loki	53
3.2	Docker commands	55
3.2.1	Show containers	55
3.2.2	Copy files to container	55
3.2.3	Enter container	55
3.2.4	Images names	55
3.2.5	Delete image	55
3.2.6	Stop container	56
3.2.7	Delete container	56
3.3	Launching parameters description	58
3.3.1	Launching services parameters	58
3.3.2	Creating DB parameters	61
3.4	Logging to server	62
3.4.1	Create logs directory	62
3.4.2	Logging activation	62
3.4.3	Mounting directories with logs when starting services	63
3.5	Docker log rotation	65
3.6	Set custom InfluxDB settings	66
3.7	Use Python Matcher with Python Matcher Proxy	68
3.7.1	Python Matcher proxy container launch	68
3.8	System scaling	69
3.8.1	Launching several containers	70
3.9	VLMatch for Oracle	72

## Default ports for services

<b>Service name</b>	<b>Port</b>
LUNA PLATFORM API	5000
LUNA PLATFORM Admin	5010
LUNA PLATFORM Image Store	5020
LUNA PLATFORM Faces	5030
LUNA PLATFORM Events	5040
LUNA PLATFORM Tasks	5050
LUNA PLATFORM Tasks Worker	5051
LUNA PLATFORM Configurator	5070
LUNA PLATFORM Sender	5080
LUNA PLATFORM Handlers	5090
LUNA PLATFORM Python Matcher	5100
LUNA PLATFORM Licenses	5120
LUNA PLATFORM Backport 4	5130
LUNA PLATFORM Backport 3	5140
LUNA PLATFORM Accounts	5170
LUNA PLATFORM Lambda	5210
LUNA PLATFORM Remote SDK	5220
LUNA PLATFORM 3 User Interface	4100
LUNA PLATFORM 4 User Interface	4200
Oracle DB	1521
PostgreSQL	5432
Redis DB	6379
InfluxDB	8086
Grafana	3000

## Configuration names for services

The table below includes the service names in the Configurator service. Use these parameters to configure your services.

<b>Service</b>	<b>Service name in Configurator</b>
API	luna-api
Licenses	luna-licenses
Faces	luna-faces
Image Store	luna-image-store
Accounts	luna-accounts
Tasks	luna-tasks
Events	luna-events
Sender	luna-sender
Admin	luna-admin
Remote SDK	luna-remote-sdk
Handlers	luna-handlers
Lambda	luna-lambda
Python Matcher	luna-python-matcher
Backport 3	luna-backport3
Backport 4	luna-backport4

Settings for the Configurator service are set in its configuration file.

## Introduction

This document describes the general steps for upgrading from LUNA PLATFORM 4 distribution (version 4.5.4) to LUNA PLATFORM 5 with Backport 4 service. See the “Backports” section in administrator manual for information about the Backport 4 service.

**Note:** This document has been tested on version v.5.64.0.

This document includes an example of LUNA PLATFORM deployment. It implements LUNA PLATFORM minimum power operating for demonstration purposes and cannot be used for the production system.

You should update LUNA PLATFORM to the version 4.5.4 if you have an earlier version. Then you should perform the migration.

This document describes migration from LUNA PLATFORM 4.5.4 installed in the default configuration. Note that your LUNA PLATFORM configuration and scaling may differ. In this case, use this manual as an example of the general approach to LUNA PLATFORM migration.

The document describes installation of all the services on a single service.

A network license is required to use the LUNA PLATFORM in Docker containers. The license is provided by VisionLabs on request separately from the delivery. The license key is created using the fingerprint of the system. This fingerprint is created based on information about the hardware characteristics of the server. Thus, the received license key will work only on the same server from which the system fingerprint was obtained. LUNA PLATFORM can be activated using one of two utilities — HASP or Guardant. The section “[License update](#)” provides useful links to instructions for activating the license key for each method.

The instructions provide an example of launching the PostgreSQL 16 database in a Docker container from the VisionLabs registry. The LUNA PLATFORM 4.5.4 installation documentation provided an example of using PostgreSQL version 3.3.8. PostgreSQL database migration is not described in this documentation.

To deploy the LUNA PLATFORM, follow the steps in the following sections:

- “[Before upgrade](#)” — Actions for unpacking archives, preparing directories, configuring licenses, etc. Some actions may be optional.
- “[Services launch](#)” — Actions to migrate databases and launch Docker containers with LUNA PLATFORM services.

The “[Additional Information](#)” section provides useful information on describing service launch parameters, Docker commands, enabling Grafana for monitoring visualization, etc.

A license file is required for LUNA PLATFORM activation. The file is provided by VisionLabs separately upon request.

All actions described in this manual must be performed by the **root** user. This document does not describe the creation of the user with administrator privileges and the following installation by this user.

## 1 Before upgrade

Make sure that you are the **root** user before upgrade!

Before upgrading the LUNA PLATFORM, you must perform the following actions:

1. [Introduce yourself with accounts migration notes.](#)
2. [Create backups.](#)
3. [Delete old symbolic link.](#)
4. [Unpack the distribution of the new version of LUNA PLATFORM.](#)
5. [Create new symbolic link.](#)
6. [Change group and owner for new directories.](#)
7. [Move Image Store buckets.](#)
8. [Configure SELinux and Firewall](#) if not previously configured.
9. [Create log directories for new services](#), if logging to a file was previously used.
10. [Update license.](#)
11. [Install Docker.](#)
12. [Set up GPU computing](#) if you plan to use GPU.
13. [Login to VisionLabs registry](#) if authorization was not previously performed.
14. [Remove LUNA PLATFORM 4 containers.](#)

## 1.1 Accounts migration notes

All accounts created using the Admin service will be automatically migrated. The administrator account will be assigned the type “admin”, and accounts created by requesting the resource “/accounts” will be assigned the type “advanced\_user”. The email address will be used as login and password. The name of the organization will be written in the “description” field.

Old account	New account
Organization name: VisionLabs	login: example@visionlabs.ai
E-mail address: example@visionlabs.ai	password: example@visionlabs.ai
Account id: e8531a5b-a429-4980-8d04-b38d8c220409	description: VisionLabs
	account_id: e8531a5b-a429-4980-8d04-b38d8c220409
	account_type: admin

In order to retain the ability to use the data created earlier by specifying the “account\_id” in the “Luna-Account-Id” header, it is necessary in the account creation request specify “login”, “password”, “account\_type” and the old identifier “account\_id” in the “Luna-Account-Id” header of the request. Thus, the old “account\_id” will be linked to the account being created.

Examples of linking account and creating new account are given in the [“Account creation”](#) section.

## 1.2 Backups creation

Create backups for all the databases used with LUNA PLATFORM before performing the migration procedures. You can restore your data if any problems occur during the migration.

It is recommended to create backups for Image Store buckets.

Backups creation for databases and buckets is not described in this document.

## 1.3 Delete old symbolic link

Go to the “luna” directory.

```
cd /var/lib/luna
```

Delete the “current” symbolic link.

```
rm -f current
```

## 1.4 Distribution unpacking

The distribution package is an archive **luna\_v.5.67.0**, where **v.5.67.0** is a numerical identifier, describing the current LUNA PLATFORM version.

The archive includes configuration files, required for installation and exploitation. It does not include Docker images for the services. They should be downloaded from the Internet.

Move the distribution package to the directory on your server before the installation. For example, move the files to `/root/` directory. The directory should not contain any other distribution or license files except the target ones.

Move the distribution to the created directory.

```
mv /root/luna_v.5.67.0.zip /var/lib/luna
```

Install the unzip archiver if it is necessary.

```
yum install -y unzip
```

Go to the folder with distribution.

```
cd /var/lib/luna
```

Unzip files.

```
unzip luna_v.5.67.0.zip
```

## 1.5 Symbolic link creation

Create a symbolic link.

The link indicates that the current version of the distribution file is used to run LUNA PLATFORM.

```
ln -s luna_v.5.67.0 current
```

## 1.6 Changing group and owner for directories

LP services are launched inside the containers by the “luna” user. Therefore, it is required to set permissions for this user to use the mounted volumes.

Go to the LP “example-docker” directory.

```
cd /var/lib/luna/current/example-docker/
```

Create a directory to store settings.

```
mkdir luna_configurator/used_dumps
```

Set permissions for the user with UID 1001 and group 0 to use the mounted directories.

```
chown -R 1001:0 luna_configurator/used_dumps
```

## 1.7 Move Image Store buckets

LUNA PLATFORM 5 is supposed to store buckets in the root directory `/var/lib/luna/` to simplify the process of subsequent updates.

Create a directory to store Image Store buckets.

```
mkdir -p /var/lib/luna/image_store
```

Move the contents of the Image Store bucket directory to the new bucket storage directory.

```
mv /var/lib/luna/luna_v.4.5.4/example-docker-compose/image_store/* /var/lib/luna/image_store
```

Set permissions for the user with UID 1001 and group 0 to use the mounted directories.

```
chown -R 1001:0 /var/lib/luna/image_store
```

## 1.8 SELinux and Firewall

You must configure SELinux and Firewall so that they do not block LUNA PLATFORM services.

SELinux and Firewall configurations are not described in this guide.

**If SELinux and Firewall are not configured, the installation cannot be performed.**

## 1.9 Create log directory for new services

**Skip this section if no logs were previously stored on the server.**

In the version of LUNA PLATFORM 5, new services have appeared for which you need to create directories with logs.

See “[Logging to server](#)” section if you have not previously used logging to a file, but want to enable it.

Following are the commands to create directories for all existing services. These commands will create and assign permissions only to missing directories.

```
mkdir -p /tmp/logs/configurator /tmp/logs/image-store /tmp/logs/accounts /
tmp/logs/faces /tmp/logs/licenses /tmp/logs/events /tmp/logs/python-
matcher /tmp/logs/handlers /tmp/logs/remote-sdk /tmp/logs/tasks /tmp/logs
/tasks-worker /tmp/logs/sender /tmp/logs/api /tmp/logs/admin /tmp/logs/
backport3 /tmp/logs/backport4
```

```
chown -R 1001:0 /tmp/logs/configurator /tmp/logs/image-store /tmp/logs/
accounts /tmp/logs/faces /tmp/logs/licenses /tmp/logs/events /tmp/logs/
python-matcher /tmp/logs/handlers /tmp/logs/remote-sdk /tmp/logs/tasks /
tmp/logs/tasks-worker /tmp/logs/sender /tmp/logs/api /tmp/logs/admin /tmp
/logs/backport3 /tmp/logs/backport4
```

If you need to use the Python Matcher Proxy service, then you need to additionally create the `/tmp/logs/python-matcher-proxy` directory and set its permissions.

## 1.10 License update

To update the license, follow these steps:

- Follow the steps from [license activation manual](#).
- Set settings for [HASP](#) license or [Guardant](#) license before starting Licenses container.

### 1.10.1 Actions from License activation manual

Open the license activation manual and follow the necessary steps.

**Note:** This action is mandatory. The license will not work without following the steps to activate the license from the corresponding manual.

**Note.** When updating Guardant Control Center, you must re-issue the license key.

## 1.11 Docker installation

The Docker installation is described in the [official documentation](#).

**Note:** Docker version 25.0.3 was used when testing this instruction. It is not guaranteed to work with higher versions of Docker.

Quick installation commands are listed below.

Check the official documentation for updates if you have any problems with the installation.

Install dependencies:

```
yum install -y yum-utils device-mapper-persistent-data lvm2
```

Add repository:

```
yum-config-manager --add-repo https://download.docker.com/linux/centos/  
docker-ce.repo
```

Install Docker:

```
yum -y install docker-ce docker-ce-cli containerd.io
```

Launch Docker:

```
systemctl start docker
```

```
systemctl enable docker
```

Check Docker status:

```
systemctl status docker
```

## 1.12 Calculations using GPU

You can use GPU for the general calculations performed by Remote SDK.

**Skip this section if you are not going to utilize GPU for your calculations.**

You need to install NVIDIA Container Toolkit to use GPU with Docker containers. The example of the installation is given below.

```
distribution=$(. /etc/os-release;echo $ID$VERSION_ID)
```

```
curl -s -L https://nvidia.github.io/nvidia-docker/$distribution/nvidia-docker.repo | tee /etc/yum.repos.d/nvidia-docker.repo
```

```
yum install -y nvidia-container-toolkit
```

```
systemctl restart docker
```

Check the NVIDIA Container toolkit operating by running a base CUDA container (this container is not provided in the LP distribution and should be downloaded from the Internet):

```
docker run --rm --gpus all nvidia/cuda:11.4.3-base-centos7 nvidia-smi
```

See the [NVIDIA documentation](#) for additional information.

Attributes extraction on the GPU is engineered for maximum throughput. The input images are processed in batches. This reduces computation cost per image but does not provide the shortest latency per image.

GPU acceleration is designed for high load applications where request counts per second consistently reach thousands. It won't be beneficial to use GPU acceleration in non-extensively loaded scenarios where latency matters.

## 1.13 Login to registry

When launching containers, you should specify a link to the image required for the container launching. This image will be downloaded from the VisionLabs registry. Before that, you should login to the registry.

Login and password can be requested from the VisionLabs representative.

Enter login <username>.

```
docker login dockerhub.visionlabs.ru --username <username>
```

After running the command, you will be prompted for a password. Enter password.

In the `docker login` command, you can enter the login and password at the same time, but this does not guarantee security because the password can be seen in the command history.

#### 1.14 Remove LUNA PLATFORM 4 containers

Use the following command to stop and delete the default LUNA PLATFORM 4.5.3 containers.

You should remove all the containers of LUNA PLATFORM services if you have started a different number of containers or they have other names.

```
docker container rm -f admin api sender tasks tasks-worker events luna-  
matcher luna-detector luna-extractor licenses faces_2 faces_1 image-store  
configurator influxdb
```

It is also recommended to remove NGINX or edit its settings, as this instruction does not involve scaling using NGINX.

```
docker container rm -f nginx
```

## 2 Services launch

This section gives examples for:

- Databases tables migration.
- Buckets creation.
- Launching of containers.

LUNA PLATFORM services must be launched in the following sequence:

- Databases, Balancers, HASP service and other third-party party software.
- [Configurator](#)
- [Image Store](#)
- [Accounts](#)
- [Licenses](#)
- [Faces](#)
- [Events](#)
- [Python Matcher](#)
- [Python Matcher Proxy](#). The service is disabled by default
- [Remote SDK](#)
- [Handlers](#)
- [Tasks](#)
- [Sender](#)
- [API](#)
- [Admin](#)

Next, you need to launch the Backport 4 service and its user interface:

- [Backport 4](#).
- [User Interface 4](#).

It is recommended to launch containers one by one and wait for the container status to become “up” (use the `docker ps` command).

Some of these services are optional and you can disable their use. It is recommended to use Events, Tasks, Sender and Admin services by default. See the “[Optional services usage](#)” section for details.

When launching each service, certain parameters are used, for example, `--detach`, `--network`, etc. See the section “[Launching parameters description](#)” for more detailed information about all launch parameters of LUNA PLATFORM services and databases.

See the “[Docker commands](#)” section for details about working with containers.

## 2.1 Third-party services

This section describes the launching of databases in docker containers. They must be launched before LP services.

### 2.1.1 InfluxDB

Monitoring LUNA PLATFORM services requires running the Influx 2.0.8-alpine database. Below are the commands to launch the InfluxDB container.

For more information, see the “Monitoring” section in the administrator manual.

If necessary, you can configure the visualization of monitoring data using the LUNA Dashboards service, which includes a configured Grafana data visualization system. In addition, you can launch the Grafana Loki tool for advanced work with logs. See the instructions for launching LUNA Dashboards and Grafana Loki in the “[Monitoring and logs visualization using Grafana](#)” section.

**Note:** If necessary, you can use an external InfluxDB 2.0.8-alpine. In this case, you can skip the command below, but you will have to set [custom settings](#) for each LUNA PLATFORM service.

Use the `docker run` command with these parameters:

```
docker run \  
-e DOCKER_INFLUXDB_INIT_MODE=setup \  
-e DOCKER_INFLUXDB_INIT_BUCKET=luna_monitoring \  
-e DOCKER_INFLUXDB_INIT_USERNAME=luna \  
-e DOCKER_INFLUXDB_INIT_PASSWORD=password \  
-e DOCKER_INFLUXDB_INIT_ORG=luna \  
-e DOCKER_INFLUXDB_INIT_ADMIN_TOKEN=  
    kofqt4Pfqn6o0RBtMDQqVoJLgHoxxDUmmhiAZ7JS6VmEnrqZXQhxDhad8AX9tmiJH6CjM7Y1U8p5eSEocG  
    == \  
-v /etc/localtime:/etc/localtime:ro \  
-v /var/lib/luna/influx:/var/lib/influxdb2 \  
--restart=always \  
--detach=true \  
--network=host \  
--name influxdb \  
dockerhub.visionlabs.ru/luna/influxdb:2.0.8-alpine
```

### 2.1.2 PostgreSQL

#### 2.1.2.1 Migrate PostgreSQL 9.6 to PostgreSQL 16

In LUNA PLATFORM 5, the VisionLabs image for PostgreSQL has been updated from version 9.6 to version 16.

If this image was previously used, then you need to perform the migration yourself according to [official documentation](#). If necessary, you can continue using PostgreSQL 9.6.

Mounting PostgreSQL 9.6 data into a container for PostgreSQL 16 will result in an error.

### 2.1.2.2 Launch PostgreSQL

**Note:** Make sure that the old PostgreSQL is deleted.

Use the following command to launch PostgreSQL.

```
docker run \  
--env=POSTGRES_USER=luna \  
--env=POSTGRES_PASSWORD=luna \  
--shm-size=1g \  
-v /var/lib/luna/postgresql/data:/var/lib/postgresql/data/ \  
-v /var/lib/luna/current/example-docker/postgresql/entrypoint-initdb.d:/  
    docker-entrypoint-initdb.d/ \  
-v /etc/localtime:/etc/localtime:ro \  
--name=postgres \  
--restart=always \  
--detach=true \  
--network=host \  
dockerhub.visionlabs.ru/luna/postgis-vlmatch:16
```

`-v /var/lib/luna/current/example-docker/postgresql/entrypoint-initdb.d:/docker-entrypoint-initdb.d/ \` — The “docker-entrypoint-initdb.d” script includes the commands for the creation of services databases. During database creation, a default username and password are automatically used.

`-v /var/lib/luna/current/example-docker/postgresql/data:/var/lib/postgresql/data/` — The volume command enables you to mount the “data” folder to the PostgreSQL container. The folder on the server and the folder in the container will be synchronized. The PostgreSQL data from the container will be saved to this directory.

`--network=host` — If you need to change the port for PostgreSQL, you should change this string to `-p 5440:5432`. Where the first port 5440 is the local port and 5432 is the port used inside the container.

You should create all the databases for LP services manually if you are going to use an already installed PostgreSQL.

### 2.1.3 Redis

**Note:** If you already have Redis installed, skip this step.

Use the following command to launch Redis.

```
docker run \  
-v /etc/localtime:/etc/localtime:ro \  
--name=redis \  
--restart=always \  
--detach=true \  
--network=host \  
dockerhub.visionlabs.ru/luna/redis:7.2
```

## 2.2 Configurator

### 2.2.1 Optional services usage

The listed below services are not mandatory for LP:

- Events
- Image Store
- Tasks
- Sender
- Handlers
- Python Matcher Proxy (disabled by default)
- Lambda (disabled by default)

Working with the Lambda service is possible only when deploying LUNA PLATFORM services in Kubernetes. See detailed information in the installation manual using Kubernetes.

You can disable them if their functionality is not required for your tasks.

Use the “ADDITIONAL\_SERVICES\_USAGE” section in the API service settings in the Configurator service to disable unnecessary services.

You can use the dump file provided in the distribution package to enable/disable services before Configurator launch.

```
vi /var/lib/luna/current/extras/conf/platform_settings.json
```

Disabling any of the services has certain consequences. For more information, see the “Disableable services” section of the administrator manual.

### 2.2.2 Configurator DB recreation

It is not required to migrate Configurator database as it should be created from scratch and filled in manually.

Use the following commands to delete and create the Configurator service database.

Delete the old database.

```
docker exec -it postgres psql -U luna -c "DROP DATABASE luna_configurator;"
```

Create the new database.

```
docker exec -it postgres psql -U luna -c "CREATE DATABASE luna_configurator;"
```

Grant privileges to the database user.

```
docker exec -it postgres psql -U luna -c "GRANT ALL PRIVILEGES ON DATABASE
luna_configurator TO luna;"
```

Allow user to authorize in the DB.

```
docker exec -it postgres psql -U luna -c "ALTER ROLE luna WITH LOGIN;"
```

### 2.2.3 Configurator DB tables creation

Use the `docker run` command with these parameters to create the Configurator database tables.

```
docker run \
-v /etc/localtime:/etc/localtime:ro \
-v /var/lib/luna/current/example-docker/luna_configurator/configs/
luna_configurator_postgres.conf:/srv/luna_configurator/configs/config.
conf \
-v /var/lib/luna/current/extras/conf/platform_settings.json:/srv/
luna_configurator/used_dumps/platform_settings.json \
--network=host \
-v /tmp/logs/configurator:/srv/logs \
--rm \
--entrypoint bash \
dockerhub.visionlabs.ru/luna/luna-configurator:v.2.2.18 \
-c "python3 ./base_scripts/db_create.py; cd /srv/luna_configurator/configs/
configs/; python3 -m configs.migrate --config /srv/luna_configurator/
configs/config.conf head; cd /srv; python3 ./base_scripts/db_create.py --
dump-file /srv/luna_configurator/used_dumps/platform_settings.json"
```

Here:

- `/var/lib/luna/current/extras/conf/platform_settings.json` — Enables you to specify the path to the dump file with LP configurations.
- `./base_scripts/db_create.py`; — Creates database structure.
- `python3 -m configs.migrate head`; — Performs settings migrations in Configurator DB and sets revision for migration. The revision will be required during the upgrade to the new LP5 build.
- `--dump-file /srv/luna_configurator/used_dumps/platform_settings.json` — Updates settings in the Configurator DB with values from the provided file.

## 2.2.4 Run Configurator container

Use the `docker run` command with these parameters to launch Configurator:

```
docker run \  
--env=PORT=5070 \  
--env=WORKER_COUNT=1 \  
--env=RELOAD_CONFIG=1 \  
--env=RELOAD_CONFIG_INTERVAL=10 \  
-v /etc/localtime:/etc/localtime:ro \  
-v /var/lib/luna/current/example-docker/luna_configurator/configs/  
  luna_configurator_postgres.conf:/srv/luna_configurator/configs/config.  
  conf \  
-v /tmp/logs/configurator:/srv/logs \  
--name=luna-configurator \  
--restart=always \  
--detach=true \  
--network=host \  
dockerhub.visionlabs.ru/luna/luna-configurator:v.2.2.18
```

At this stage, you can activate logging to file if you need to save them on the server (see the [“Logging to server”](#) section).

## 2.3 Image Store

### 2.3.1 Samples migrations

To migrate from LUNA PLATFORM 4 you can assign an account to all the samples in your Image Store bucket. Otherwise all the objects created for the LUNA PLATFORM 4 can be accessed within any account, and also without any account.

You can skip the following script execution if the samples should not be linked to any account and can be accessed from any account.

Create a backup of all the samples buckets before launching the following script.

You should launch the “migrate\_4\_to\_5.py” script to update account information for the stored samples.

You should use existing buckets during the samples migration script execution. Set up actual storage configurations for the Image Store service in the Configurator service user interface.

Run migration script.

```
docker run \  
--rm -t \  
-v /tmp/logs/image-store:/srv/logs \  
-v /var/lib/luna/image_store:/srv/luna_image_store/local_storage/ \  
--network=host \  
--entrypoint bash dockerhub.visionlabs.ru/luna/luna-image-store:v.3.14.2 \  
-c "python3 ./base_scripts/accounting/migrate_4_to_5.py --account_id=<  
account_id> --bucket=visionlabs-samples"
```

Here:

- `-v /var/lib/luna/image_store` — Path to the `local_storage` of the Image Store samples.
- `<account_id>` — You should specify the account ID which will have access to all the samples from the specified bucket (`visionlabs-samples`).

### 2.3.2 Image Store container launch

**Note:** If you are not going to use the Image Store service, do not launch this container and disable the service utilization in Configurator. See section “[Optional services usage](#)”.

Use the following command to launch the Image Store service:

```
docker run \  
--env=CONFIGURATOR_HOST=127.0.0.1 \  
--env=CONFIGURATOR_PORT=5070 \  
--network=host
```

```

--env=PORT=5020 \
--env=WORKER_COUNT=1 \
--env=RELOAD_CONFIG=1 \
--env=RELOAD_CONFIG_INTERVAL=10 \
-v /var/lib/luna/image_store:/srv/local_storage/ \
-v /etc/localtime:/etc/localtime:ro \
-v /tmp/logs/image-store:/srv/logs \
--name=luna-image-store \
--restart=always \
--detach=true \
--network=host \
dockerhub.visionlabs.ru/luna/luna-image-store:v.3.14.2

```

Here `-v /var/lib/luna/image_store:/srv/local_storage/` is the data from the specified folder is added to the Docker container when it is launched. All the data from the specified Docker container folder is saved to this directory.

If you already have a directory with LP buckets you should specify it instead of `/var/lib/luna/image_store/`.

### 2.3.3 Buckets creation

Buckets are required to store data in Image Store. The Image Store service should be launched before the commands execution.

When upgrading from the previous version, it is recommended to launch the bucket creation commands one more time. Hence you make sure that all the required buckets were created.

If the error with code [13006](#) appears during launching of the listed above commands, the bucket is already created.

Buckets in LP can be created in two ways:

- Using the `lis_bucket_create.py` script located in the Image Store service container.
- Using direct requests to the Image Store service.

#### Use script to create buckets

Run this script to create general buckets:

```

docker run \
-v /etc/localtime:/etc/localtime:ro \
-v /tmp/logs/api:/srv/logs \
--rm \
--network=host \
dockerhub.visionlabs.ru/luna/luna-api:v.6.29.0 \

```

```
python3 ./base_scripts/lis_bucket_create.py -ii --luna-config http://localhost:5070/1
```

If you want to specify the storage time of an object in a bucket, you can additionally specify the number of days using the `--bucket-ttl` argument. See details in the “Object lifecycle” section of the administrator manual.

If you are going to use the Tasks service, use the following command to additionally create the “task-result” in the Image Store service:

```
docker run \  
-v /etc/localtime:/etc/localtime:ro \  
-v /tmp/logs/tasks:/srv/logs \  
--rm \  
--network=host \  
dockerhub.visionlabs.ru/luna/luna-tasks:v.3.22.1 \  
python3 ./base_scripts/lis_bucket_create.py -ii --luna-config http://localhost:5070/1
```

If you are going to use the portraits, use the following command to additionally create the “portraits”.

```
docker run \  
-v /etc/localtime:/etc/localtime:ro \  
-v /tmp/logs/api:/srv/logs \  
--rm \  
--network=host \  
dockerhub.visionlabs.ru/luna/luna-backport3:v.0.11.9 \  
python3 ./base_scripts/lis_bucket_create.py -ii --luna-config http://localhost:5070/1
```

### Use direct requests

The curl utility is required for the following requests.

The “visionlabs-samples” bucket is used for face samples storage. The bucket is required for LP utilization.

```
curl -X POST http://127.0.0.1:5020/1/buckets?bucket=visionlabs-samples
```

If you want to specify the storage time of an object in a bucket, you can additionally specify the number of days using the `tll` query parameter. See details in the “Object lifecycle” section of the administrator manual.

The “portraits” bucket is used for portraits storage. The bucket is required for Backport 3 utilization.

```
curl -X POST http://127.0.0.1:5020/1/buckets?bucket=portraits
```

The “visionlabs-bodies-samples” bucket is used for human bodies samples storage. The bucket is required for LP utilization.

```
curl -X POST http://127.0.0.1:5020/1/buckets?bucket=visionlabs-bodies-samples
```

The “visionlabs-image-origin” bucket is used for source images storage. The bucket is required for LP utilization.

```
curl -X POST http://127.0.0.1:5020/1/buckets?bucket=visionlabs-image-origin
```

The “visionlabs-objects” bucket is used for objects storage. The bucket is required for LP utilization.

```
curl -X POST http://127.0.0.1:5020/1/buckets?bucket=visionlabs-objects
```

The “task-result” bucket for the Tasks service. Do not use it if you are not going to use the Tasks service.

```
curl -X POST http://127.0.0.1:5020/1/buckets?bucket=task-result
```

#### 2.3.4 Add TTL for local-buckets

**Note.** Perform the steps below only if the buckets are stored in local storage and you need to manage the lifetime of existing and/or new objects in the buckets.

In order to add TTLs for all objects in a bucket located in local storage, you must update it by specifying the `ttl` request parameter.

For example, you can add a lifetime of all objects equal to 2 days in the “visionlabs-samples” bucket using the following command:

```
curl -X PUT http://127.0.0.1:5020/1/buckets?bucket=visionlabs-samples?ttl=2
```

#### 2.3.5 Add TTL for S3 buckets

**Note:** Perform the steps below only if the buckets are stored in S3-like storage and you need to manage the lifetime of existing and/or new objects in the bucket.

In order to add TTLs for objects in buckets located in S3-like storage, a special migration script `migrate_ttl_settings.py` must be executed.

**Note:** See the “Migration to apply TTL to objects in S3” section in the administrator manual for details on migration and its specifics.

The migration script should be run with the following arguments:

- `--bucket` — Bucket name, e.g. `visionlabs-samples`.
- `--update-tags` - Whether tags should be added to all existing objects.

If the `--update-tags` argument is 1, the tags required for TTL will be added to all existing objects. The duration of the migration will depend on the number of existing objects.

If the `--update-tags` argument is 0, the tags required for TTL will not be added to all existing objects. In this case, lifecycle management for existing objects will not be available.

Tags will be added automatically to new objects after migration.

The script also needs to fill the authorization data to the S3-like storage in the configuration file and mount it to the Image Store service container.

Fill the configuration file with the following command:

```
vi /var/lib/luna/current/extras/conf/s3_bucket.conf
```

Perform the migration of buckets to the S3 storage:

```
docker run \  
-v /etc/localtime:/etc/localtime:ro \  
-v /tmp/logs/image-store:/srv/logs \  
-v /var/lib/luna/current/extras/conf/s3_bucket.conf:/srv/base_scripts/  
  migrate_ttl_settings/config.conf \  
--rm \  
--network=host \  
dockerhub.visionlabs.ru/luna/luna-image-store:v.3.14.2 \  
python3 ./base_scripts/migrate_ttl_settings/migrate_ttl_settings.py --bucket  
  =<your_bucket_name> --update-tags=<your_value>
```

## 2.4 Accounts

### 2.4.1 Admin DB transformation

**Note:** Follow the steps below only if you have used the Admin service before. Otherwise, skip this section.

By default, the Accounts service creates its own `luna_accounts` database, but if the Admin service was previously used, then the `luna_admin` should must be transformed to work with the Accounts service. To do this, you need to change the default `luna_accounts` database used by the Accounts service to `luna_admin` in the Configurator and run the data migration script.

#### 2.4.1.1 Admin DB migration

Run migration script to update the structure of the Admin database and transform it to work with the Accounts service.

Note that after the migration, the database will be named `luna_admin`, but will be used exclusively by the Accounts service.

It is recommended to create the back up of your database before applying any changes.

```
docker run \  
-v /etc/localtime:/etc/localtime:ro \  
-v /tmp/logs/accounts:/srv/logs \  
--rm \  
--network=host \  
dockerhub.visionlabs.ru/luna/luna-accounts:v.0.3.9 \  
alembic -x luna-config=http://127.0.0.1:5070/1 upgrade head
```

### 2.4.2 Accounts DB tables creation

**Note:** Perform the steps below only if you are launching the Accounts service for the first time and have not used the Admin service before. If you used the Admin service before, skip this section and make sure you have completed the steps in the “[Admin DB transformation](#)” section.

Use the following command to create Accounts DB tables:

```
docker run \  
-v /etc/localtime:/etc/localtime:ro \  
-v /tmp/logs/accounts:/srv/logs \  
--rm \  
--network=host \  
dockerhub.visionlabs.ru/luna/luna-accounts:v.0.3.9 \  
python3 ./base_scripts/db_create.py --luna-config http://localhost:5070/1
```

### 2.4.3 Accounts container launch

Use the following command to launch the service:

```
docker run \  
--env=CONFIGURATOR_HOST=127.0.0.1 \  
--env=CONFIGURATOR_PORT=5070 \  
--env=PORT=5170 \  
--env=WORKER_COUNT=1 \  
--env=RELOAD_CONFIG=1 \  
--env=RELOAD_CONFIG_INTERVAL=10 \  
-v /etc/localtime:/etc/localtime:ro \  
-v /tmp/logs/accounts:/srv/logs \  
--name=luna-accounts \  
--restart=always \  
--detach=true \  
--network=host \  
dockerhub.visionlabs.ru/luna/luna-accounts:v.0.3.9
```

## 2.5 Licenses

**Note:** To use a trial license, it is required to launch the Licenses service on the same server where trial license is being used.

### 2.5.1 Specify license settings using Configurator

Follow the steps below to set the settings for [HASP-key](#) or [Guardant-key](#).

#### 2.5.1.1 Specify HASP license settings

**Note:** Perform these actions only if the HASP key is used. See the [“Specify Guardant license settings”](#) section if the Guardant key is used.

To set the license server address, follow these steps:

- Go to the Configurator service interface `http://<configurator_server_ip>:5070/`.
- Specify the “LICENSE\_VENDOR” value in the “Setting name” field and click “Apply Filters”.
- Set the IP address of the server with your HASP key in the field “server\_address” in the format “127.0.0.1”.
- Click “Save”.

If the license is activated using the HASP key, then two parameters “vendor” and “server\_address” must be specified. If you want to change the HASP protection to Guardant, then you need to add the “license\_id” field.

#### 2.5.1.2 Specify Guardant license settings

**Note:** Perform these actions only if the Guardant key is used. See the [“Specify HASP license settings”](#) section if the HASP key is used.

To set the license server address, follow these steps:

- Go to the Configurator service interface `http://<configurator_server_ip>:5070/`.
- Enter the value “LICENSE\_VENDOR” in the “Setting name” field and click “Apply Filters”.
- Set the IP address of the server with your Guardant key in the “server\_address” field.
- Set the license ID in the format `0x<your_license_id>`, obtained in the section “Save license ID” in the License activation manual, in the “license\_id” field.
- Click “Save”.

If the license is activated using the Guardant key, then three parameters “vendor”, “server\_address”

and “license\_id” must be specified. If you want to change the Guardant protection to HASP, then you need to delete the “license\_id” field.

### 2.5.2 Licenses container launch

Use the following command to launch the service:

```
docker run \  
--env=CONFIGURATOR_HOST=127.0.0.1 \  
--env=CONFIGURATOR_PORT=5070 \  
--env=PORT=5120 \  
--env=WORKER_COUNT=1 \  
--env=RELOAD_CONFIG=1 \  
--env=RELOAD_CONFIG_INTERVAL=10 \  
-v /etc/localtime:/etc/localtime:ro \  
-v /tmp/logs/licenses:/srv/logs \  
--name=luna-licenses \  
--restart=always \  
--detach=true \  
--network=host \  
dockerhub.visionlabs.ru/luna/luna-licenses:v.0.10.18
```

## 2.6 Faces

### 2.6.1 Faces database migration

You need to execute migration scripts to update your Faces database structure.

It is recommended to create the back up of your database before applying any changes.

Run the following command to perform the Faces DB migration.

```
docker run \  
-v /etc/localtime:/etc/localtime:ro \  
-v /tmp/logs/faces:/srv/logs \  
--rm \  
--network=host \  
dockerhub.visionlabs.ru/luna/luna-faces:v.4.11.9 \  
alembic -x luna-config=http://127.0.0.1:5070/1 upgrade head
```

### 2.6.2 Faces container launch

Use the following command to launch the service:

```
docker run \  
--env=CONFIGURATOR_HOST=127.0.0.1 \  
--env=CONFIGURATOR_PORT=5070 \  
--env=PORT=5030 \  
--env=WORKER_COUNT=2 \  
--env=RELOAD_CONFIG=1 \  
--env=RELOAD_CONFIG_INTERVAL=10 \  
-v /etc/localtime:/etc/localtime:ro \  
-v /tmp/logs/faces:/srv/logs \  
--name=luna-faces \  
--restart=always \  
--detach=true \  
--network=host \  
dockerhub.visionlabs.ru/luna/luna-faces:v.4.11.9
```

### 2.6.3 Add VLMatch function to Faces database

The VLMatch function should be applied to the PostgreSQL DB.

Define the function inside the Faces database.

```
docker exec -it postgres psql -U luna -d luna_faces -c "CREATE OR REPLACE
FUNCTION VLMatch(bytea, bytea, int) RETURNS float8 AS '/srv/VLMatchSource
.so', 'VLMatch' LANGUAGE C PARALLEL SAFE;";
```

Test function by sending the following request to the service database.

```
docker exec -it postgres psql -U luna -d luna_faces -c "SELECT VLMatch('\
x1234567890123456789012345678901234567890123456789012345678901234'::bytea
, '\x0123456789012345678901234567890123456789012345678901234567890123'::
bytea, 32);"
```

The result returned by the database must be “0.4765625”.

## 2.7 Events

### 2.7.1 Events database migration

You need to execute migration scripts to update your Events database structure.

It is recommended to create the back up of your database before applying any changes.

```
docker run \  
-v /etc/localtime:/etc/localtime:ro \  
-v /tmp/logs/events:/srv/logs \  
--rm \  
--network=host \  
dockerhub.visionlabs.ru/luna/luna-events:v.4.12.9 \  
alembic -x luna-config=http://127.0.0.1:5070/1 upgrade head
```

### 2.7.2 Events container launch

**Note:** If you are not going to use the Events service, do not launch this container and disable the service utilization in Configurator. See section “[Optional services usage](#)”.

Use the following command to launch the service:

```
docker run \  
--env=CONFIGURATOR_HOST=127.0.0.1 \  
--env=CONFIGURATOR_PORT=5070 \  
--env=PORT=5040 \  
--env=WORKER_COUNT=1 \  
--env=RELOAD_CONFIG=1 \  
--env=RELOAD_CONFIG_INTERVAL=10 \  
-v /etc/localtime:/etc/localtime:ro \  
-v /tmp/logs/events:/srv/logs \  
--name=luna-events \  
--restart=always \  
--detach=true \  
--network=host \  
dockerhub.visionlabs.ru/luna/luna-events:v.4.12.9
```

### 2.7.3 Add VLMatch function to Events database

The VLMatch function should be applied to the PostgreSQL DB.

Define the function inside the Events database.

```
docker exec -it postgres psql -U luna -d luna_events -c "CREATE OR REPLACE
    FUNCTION VLMatch(bytea, bytea, int) RETURNS float8 AS '/srv/VLMatchSource
        .so', 'VLMatch' LANGUAGE C PARALLEL SAFE;";
```

Test function within call.

```
docker exec -it postgres psql -U luna -d luna_events -c "SELECT VLMatch('\
    x1234567890123456789012345678901234567890123456789012345678901234'::bytea
        , '\x0123456789012345678901234567890123456789012345678901234567890123'::
        bytea, 32);"
```

The result returned by the database must be “0.4765625”.

## 2.8 Python Matcher services

For matching tasks, you can use either only the Python Matcher service, or additionally use the Python Matcher Proxy service, which redirects matching requests to either the Python Matcher service or matching plugins. This section describes how to use Python Matcher without Python Matcher Proxy.

You need to use the Python Matcher Proxy service only if you are going to use matching plugins. Using Python Matcher Proxy and running the corresponding docker container are described in the [“Use Python Matcher with Python Matcher Proxy”](#) section.

See the description and usage of matching plugins in the administrator manual.

### 2.8.1 Use Python Matcher without Python Matcher Proxy

The Python Matcher service with matching by the Faces DB is enabled by default after launching.

The Python Matcher service with matching by the Events is also enabled by default. You can disable it by specifying “USE\_LUNA\_EVENTS = 0” in the “ADDITIONAL\_SERVICES\_USAGE” settings of Configurator (see [“Optional services usage”](#) section). Thus, the Events service will not be used for LUNA PLATFORM.

The Python Matcher that matches using the matcher library is enabled when “CACHE\_ENABLED” is set to “true” in the “DESCRIPTORS\_CACHE” setting.

A single image is downloaded for the Python Matcher service and the Python Matcher Proxy service.

### 2.8.2 Python Matcher container launch

Use the following command to launch the service:

```
docker run \  
--env=CONFIGURATOR_HOST=127.0.0.1 \  
--env=CONFIGURATOR_PORT=5070 \  
--env=PORT=5100 \  
--env=WORKER_COUNT=1 \  
--env=RELOAD_CONFIG=1 \  
--env=RELOAD_CONFIG_INTERVAL=10 \  
-v /etc/localtime:/etc/localtime:ro \  
-v /tmp/logs/python-matcher:/srv/logs \  
--name=luna-python-matcher \  
--restart=always \  
--detach=true \  
--network=host \  
dockerhub.visionlabs.ru/luna/luna-python-matcher:v.1.9.9
```

## 2.9 Remote SDK

### 2.9.1 Remote SDK container launch

You can run the Remote SDK service utilizing CPU (set by default) or GPU.

By default, the Remote SDK service is launched with all estimators and detectors enabled. If necessary, you can disable the use of some estimators or detectors when launching the Remote SDK container. Disabling unnecessary estimators enables you to save RAM or GPU memory, since when the Remote SDK service launches, the possibility of performing these estimates is checked and neural networks are loaded into memory. If you disable the estimator or detector, you can also remove its neural network from the Remote SDK container. See the “Enable/disable several estimators and detectors” section of the administrator manual for more information.

Run the Remote SDK service using one of the following commands according to the utilized processing unit.

#### 2.9.1.1 Run Remote SDK utilizing CPU

Use the following command to launch the Remote SDK service using CPU:

```
docker run \  
--env=CONFIGURATOR_HOST=127.0.0.1 \  
--env=CONFIGURATOR_PORT=5070 \  
--env=PORT=5220 \  
--env=WORKER_COUNT=1 \  
--env=RELOAD_CONFIG=1 \  
--env=RELOAD_CONFIG_INTERVAL=10 \  
-v /etc/localtime:/etc/localtime:ro \  
-v /tmp/logs/remote-sdk:/srv/logs \  
--network=host \  
--name=luna-remote-sdk \  
--restart=always \  
--detach=true \  
dockerhub.visionlabs.ru/luna/luna-remote-sdk:v.0.6.0
```

#### 2.9.1.2 Run Remote SDK utilizing GPU

The Remote SDK service does not utilize GPU by default. If you are going to use the GPU, then you should enable its use for the Remote SDK service in the Configurator service.

If you need to use the GPU for all estimators and detectors at once, then you need to use the “global\_device\_class” parameter in the “LUNA\_REMOTE\_SDK\_RUNTIME\_SETTINGS” section. All estimators and detectors will use the value of this parameter if the “device\_class” parameter of their

settings like "LUNA\_REMOTE\_SDK\_<estimator-or-detector-name>\_SETTINGS.runtime\_settings" is set to "global" (by default for all estimators and detectors).

If you need to use the GPU for a specific estimator or detector, then you need to use the "device\_class" parameter in sections like "LUNA\_REMOTE\_SDK\_<estimator/detector-name>\_SETTINGS.runtime\_settings".

See section "[Calculations using GPU](#)" for additional requirements for GPU utilization.

Use the following command to launch the Remote SDK service using GPU:

```
docker run \  
--env=CONFIGURATOR_HOST=127.0.0.1 \  
--env=CONFIGURATOR_PORT=5070 \  
--env=PORT=5220 \  
--env=WORKER_COUNT=1 \  
--env=RELOAD_CONFIG=1 \  
--env=RELOAD_CONFIG_INTERVAL=10 \  
--gpus device=0 \  
-v /etc/localtime:/etc/localtime:ro \  
-v /tmp/logs/remote-sdk:/srv/logs \  
--network=host \  
--name=luna-remote-sdk \  
--restart=always \  
--detach=true \  
dockerhub.visionlabs.ru/luna/luna-remote-sdk:v.0.6.0
```

Here `--gpus device=0` is the parameter specifies the used GPU device and enables GPU utilization. A single GPU can be utilized per Remote SDK instance. Multiple GPU utilization per instance is not available.

### 2.9.1.3 Run slim version of Remote SDK

You can run a slim version of the Remote SDK service that contains only configuration files without neural networks. It is assumed that the user himself will add the neural networks he needs to the container.

**The launch of the slim version of the Remote SDK service is intended for advanced users.**

To successfully launch the Remote SDK container with a custom set of neural networks, you need to perform the following actions:

- Request the required neural networks from VisionLabs.
- Place neural networks in a folder with LUNA PLATFORM installed.
- Assign appropriate rights to neural network files.
- Mount neural network files to the `/srv/fsdk/data` folder of the Remote SDK container.
- Using the arguments of the variable "EXTEND\_CMD" to explicitly specify which of the neural networks should be used.

Using the “enable-all-estimators-by-default” flag for the “EXTEND\_CMD” variable, you can disable the use of all neural networks (estimators) by default, and then use special flags to explicitly specify which neural networks should be used. If you do not specify this flag or set the value “--enable-all-estimators-by-default=1”, the Remote SDK service will try to find all neural networks in the container. If one of the neural networks is not found, the Remote SDK service will not start.

List of available estimators:

<b>Argument</b>	<b>Description</b>
--enable-all-estimators-by-default	Enable all estimators by default.
--enable-human-detector	Simultaneous detector of bodies and bodies.
--enable-face-detector	Face detector.
--enable-body-detector	Body detector.
--enable-face-landmarks5-estimator	Face landmarks5 estimator.
--enable-face-landmarks68-estimator	Face landmarks68 estimator.
--enable-head-pose-estimator	Head pose estimator.
--enable-liveness-estimator	Liveness estimator.
--enable-fisheye-estimator	FishEye effect estimator.
--enable-face-detection-background-estimator	Image background estimator.
--enable-face-warp-estimator	Face sample estimator.
--enable-body-warp-estimator	Body sample estimator.
--enable-quality-estimator	Image quality estimator.
--enable-image-color-type-estimator	Face color type estimator.
--enable-face-natural-light-estimator	Natural light estimator.
--enable-eyes-estimator	Eyes estimator.
--enable-gaze-estimator	Gaze estimator.
--enable-mouth-attributes-estimator	Mouth attributes estimator.
--enable-emotions-estimator	Emotions estimator.
--enable-mask-estimator	Mask estimator.
--enable-glasses-estimator	Glasses estimator.
--enable-eyebrow-expression-estimator	Eyebrow estimator.
--enable-red-eyes-estimator	Red eyes estimator.
--enable-headwear-estimator	Headwear estimator.

Argument	Description
<code>--enable-basic-attributes-estimator</code>	Basic attributes estimator.
<code>--enable-face-descriptor-estimator</code>	Face descriptor extraction estimator.
<code>--enable-body-descriptor-estimator</code>	Body descriptor extraction estimator.
<code>--enable-body-attributes-estimator</code>	Body attributes estimator.
<code>--enable-people-count-estimator</code>	People count estimator.
<code>--enable-deepfake-estimator</code>	Deepfake estimator.

See the detailed information on enabling and disabling certain estimators in the section “Enable/disable several estimators and detectors” of the administrator manual.

Below is an example of a command to assign rights to a neural network file:

```
chown -R 1001:0 /var/lib/luna/current/<neural_network_name>.plan
```

Example of a command to run Remote SDK container with mounting neural networks for face detection and face descriptor extraction:

```
docker run \
--env=CONFIGURATOR_HOST=127.0.0.1 \
--env=CONFIGURATOR_PORT=5070 \
--env=PORT=5220 \
--env=WORKER_COUNT=1 \
--env=RELOAD_CONFIG=1 \
--env=RELOAD_CONFIG_INTERVAL=10 \
--env=EXTEND_CMD="--enable-all-estimators-by-default=0 --enable-face-
detector=1 --enable-face-descriptor-estimator=1" \
-v /var/lib/luna/current/cnn59b_cpu-avx2.plan:/srv/fsdk/data/cnn59b_cpu-avx2
.plan \
-v /var/lib/luna/current/FaceDet_v3_a1_cpu-avx2.plan:/srv/fsdk/data/
FaceDet_v3_a1_cpu-avx2.plan \
-v /var/lib/luna/current/FaceDet_v3_redetect_v3_cpu-avx2.plan:/srv/fsdk/data
/FaceDet_v3_redetect_v3_cpu-avx2.plan \
-v /var/lib/luna/current/slnet_v3_cpu-avx2.plan:/srv/fsdk/data/slnet_v3_cpu-
avx2.plan \
-v /var/lib/luna/current/LNet_precise_v2_cpu-avx2.plan:/srv/fsdk/data/
LNet_precise_v2_cpu-avx2.plan \
-v /etc/localtime:/etc/localtime:ro \
-v /tmp/logs/remote-sdk:/srv/logs \
```

```
--network=host \  
--name=luna-remote-sdk \  
--restart=always \  
--detach=true \  
dockerhub.visionlabs.ru/luna/luna-remote-sdk:v.0.6.0
```

## 2.10 Handlers

**Note:** If you are not going to use the Handlers service, do not launch this container and disable the service utilization in Configurator. See section “[Optional services usage](#)”.

### 2.10.1 Change the used database for Handlers

The database used for the Handlers service in LUNA PLATFORM 5 is the same database that was used for the API service in LUNA PLATFORM 4.

You should change the database used for the Handlers service to the “luna\_api” database in the Configurator service.

- Go to the Configurator interface ([http://<server\\_address>:5070](http://<server_address>:5070) by default).
- Specify the LUNA\_HANDLERS\_DB in the “Setting name” field of the filter and press [Apply filters] or select “luna-handlers” in the “Service name field” and find the setting there.
- Set the “db\_name”: “luna\_api” parameter in the value field.
- Press [Save].

### 2.10.2 Handlers database migration

You need to execute migration scripts to update your Handlers database structure.

It is recommended to create the back up of your database before applying any changes.

```
docker run \  
-v /etc/localtime:/etc/localtime:ro \  
-v /tmp/logs/handlers:/srv/logs \  
--rm \  
--network=host \  
dockerhub.visionlabs.ru/luna/luna-handlers:v.3.6.0 \  
alembic -x luna-config=http://127.0.0.1:5070/1 upgrade head
```

### 2.10.3 Handlers container launch

Use the following command to launch the service:

```
docker run \  
--env=CONFIGURATOR_HOST=127.0.0.1 \  
--env=CONFIGURATOR_PORT=5070 \  
--env=PORT=5090 \  
--env=WORKER_COUNT=1 \  

```

```
--env=RELOAD_CONFIG=1 \  
--env=RELOAD_CONFIG_INTERVAL=10 \  
-v /etc/localtime:/etc/localtime:ro \  
-v /tmp/logs/handlers:/srv/logs \  
--name=luna-handlers \  
--restart=always \  
--detach=true \  
--network=host \  
dockerhub.visionlabs.ru/luna/luna-handlers:v.3.6.0
```

## 2.11 Tasks

**Note:** If you are not going to use the Tasks service, do not launch the Tasks container and the Tasks Worker container. Disable the service utilization in Configurator. See section “[Optional services usage](#)”.

### 2.11.1 Tasks database migration

You need to execute migration scripts to update your Tasks database structure.

It is recommended to create the back up of your database before applying any changes.

```
docker run \  
-v /etc/localtime:/etc/localtime:ro \  
-v /tmp/logs/tasks:/srv/logs \  
--rm \  
--network=host \  
dockerhub.visionlabs.ru/luna/luna-tasks:v.3.22.1 \  
alembic -x luna-config=http://127.0.0.1:5070/1 upgrade head
```

### 2.11.2 Tasks and Tasks Worker containers launch

Tasks service image includes the Tasks service and the Tasks Worker. They both must be launched.

The “task-result” bucket should be created for the Tasks service before the service launch. The buckets creation is described in the “[Buckets creation](#)”.

If it is necessary to use the Estimator task using a network disk, then you should first mount the directory with images from the network disk into special directories of Tasks and Tasks Worker containers. See the “Estimator task” section in the administrator manual for details.

#### 2.11.2.1 Tasks Worker launch

Use the following command to launch the service:

```
docker run \  
--env=CONFIGURATOR_HOST=127.0.0.1 \  
--env=CONFIGURATOR_PORT=5070 \  
--env=PORT=5051 \  
--env=WORKER_COUNT=1 \  
--env=RELOAD_CONFIG=1 \  
--env=RELOAD_CONFIG_INTERVAL=10 \  
--env=SERVICE_TYPE="tasks_worker" \  
-v /etc/localtime:/etc/localtime:ro \  

```

```
-v /tmp/logs/tasks-worker:/srv/logs \  
--name=luna-tasks-worker \  
--restart=always \  
--detach=true \  
--network=host \  
dockerhub.visionlabs.ru/luna/luna-tasks:v.3.22.1
```

### 2.11.2.2 Tasks launch

Use the following command to launch the service:

```
docker run \  
--env=CONFIGURATOR_HOST=127.0.0.1 \  
--env=CONFIGURATOR_PORT=5070 \  
--env=PORT=5050 \  
--env=WORKER_COUNT=1 \  
--env=RELOAD_CONFIG=1 \  
--env=RELOAD_CONFIG_INTERVAL=10 \  
-v /etc/localtime:/etc/localtime:ro \  
-v /tmp/logs/tasks:/srv/logs \  
--name=luna-tasks \  
--restart=always \  
--detach=true \  
--network=host \  
dockerhub.visionlabs.ru/luna/luna-tasks:v.3.22.1
```

## 2.12 Sender

### 2.12.1 Sender container launch

**Note:** If you are not going to use the Sender service, do not launch this container and disable the service utilization in Configurator. See section “[Optional services usage](#)”.

Use the following command to launch the service:

```
docker run \  
--env=CONFIGURATOR_HOST=127.0.0.1 \  
--env=CONFIGURATOR_PORT=5070 \  
--env=PORT=5080 \  
--env=WORKER_COUNT=1 \  
--env=RELOAD_CONFIG=1 \  
--env=RELOAD_CONFIG_INTERVAL=10 \  
-v /etc/localtime:/etc/localtime:ro \  
-v /tmp/logs/sender:/srv/logs \  
--name=luna-sender \  
--restart=always \  
--detach=true \  
--network=host \  
dockerhub.visionlabs.ru/luna/luna-sender:v.2.11.9
```

## 2.13 API

### 2.13.1 API container launch

Use the following command to launch the service:

```
docker run \  
--env=CONFIGURATOR_HOST=127.0.0.1 \  
--env=CONFIGURATOR_PORT=5070 \  
--env=PORT=5000 \  
--env=WORKER_COUNT=1 \  
--env=RELOAD_CONFIG=1 \  
--env=RELOAD_CONFIG_INTERVAL=10 \  
--name=luna-api \  
--restart=always \  
--detach=true \  
-v /etc/localtime:/etc/localtime:ro \  
-v /tmp/logs/api:/srv/logs \  
--network=host \  
dockerhub.visionlabs.ru/luna/luna-api:v.6.29.0
```

### 2.13.2 Account creation

The account is created using an HTTP request to the “create account” resource of the API service.

You can also create an account using the Admin service. This method requires an existing login and password (or the default login and password) and enables you to create an “admin” account. See the “Admin service” section of the administrator manual for details.

To create the account using a request to the API service, you need to provide the following mandatory data:

- “login” — Email address.
- “password” — Password.
- “account\_type” — Account type (“user” or “advanced\_user”).

Create the account using your authentication details.

If you want to keep the ability to use the “account\_id” that was used as the “Luna-Account-Id” header in previous LP versions (without creating an account in the Admin service), then you need to link the old “account\_id” to the account being created.

Example of CURL-request to the “create account” resource:

```
curl --location --request POST 'http://127.0.0.1:5000/6/accounts' \  
--header 'Content-Type: application/json' \  
--header 'Luna-Account-Id: <your_old_account_id>' \  
--data '{  
  "login": "user@mail.com",  
  "password": "password",  
  "account_type": "user",  
  "description": "description"  
}'
```

It is necessary to replace the authentication data from the example with your own.

To work with tokens, you must have an account.

## 2.14 Admin

### 2.14.1 Admin container launch

**Note:** If you are not going to use the Admin service, do not launch this container.

Use the following command to launch the service:

```
docker run \  
--env=CONFIGURATOR_HOST=127.0.0.1 \  
--env=CONFIGURATOR_PORT=5070 \  
--env=PORT=5010 \  
--env=WORKER_COUNT=1 \  
--env=RELOAD_CONFIG=1 \  
--env=RELOAD_CONFIG_INTERVAL=10 \  
-v /etc/localtime:/etc/localtime:ro \  
-v /tmp/logs/admin:/srv/logs \  
--name=luna-admin \  
--restart=always \  
--detach=true \  
--network=host \  
dockerhub.visionlabs.ru/luna/luna-admin:v.5.7.1
```

Monitoring data about the number of executed requests is saved in the luna-admin bucket of the InfluxDB. To enable data saving use the following command:

```
docker exec -it luna-admin python3 ./base_scripts/influx2_cli.py  
create_usage_task --luna-config http://127.0.0.1:5070/1
```

## 2.15 Backport 4

The section describes launching of Backport 4 service.

The service is not mandatory for utilizing LP5 and is required for emulation of LP 4 API only.

### 2.15.1 Backport 4 container launch

Use the following command to launch the service:

```
docker run \  
--env=CONFIGURATOR_HOST=127.0.0.1 \  
--env=CONFIGURATOR_PORT=5070 \  
--env=PORT=5130 \  
--env=WORKER_COUNT=1 \  
--env=RELOAD_CONFIG=1 \  
--env=RELOAD_CONFIG_INTERVAL=10 \  
--name=luna-backport4 \  
--restart=always \  
--detach=true \  
-v /etc/localtime:/etc/localtime:ro \  
-v /tmp/logs/backport4:/srv/logs \  
--network=host \  
dockerhub.visionlabs.ru/luna/luna-backport4:v.1.5.9
```

## 2.15.2 User Interface 4

The User Interface 4 is used with the Backport 4 service only.

### 2.15.2.1 User Interface 4 container launch

**Note:** You should have the account with account type **user** before launching the User Interface 4 container. Its login and password in Base64 format will be used to work with the user interface.

Use the following command to launch the service:

```
docker run \  
--env=PORT=4200 \  
--env=LUNA_API_URL=http://<server_external_ip>:5130 \  
--env=BASIC_AUTH=dXNlcjBtYWlsLmNvbTpwYXNzd29yZA== \  
--name=luna-ui-4 \  
--restart=always \  
--detach=true \  
--network=host \  
-v /etc/localtime:/etc/localtime:ro \  
dockerhub.visionlabs.ru/luna/luna4-ui:v.0.1.8
```

Here:

- `--env=PORT` — Sets the port for running User Interface 4.
- `--env=BASIC_AUTH` — Sets the Basic authorization for the account which data is displayed in the user interface. It is necessary to convert `login:password` created in the section “[Account creation](#)” to Base64 format. The account type should be set to **user**.
- `--env=LUNA_API_URL` — Sets the URL of the Backport 4 service.

You should use the external IP of the service, not localhost.

You should specify the Backport 4 service port (5130 is set by default).

### 3 Additional information

This section provides the following additional information:

- [Monitoring and logs visualization using Grafana.](#)
- [Useful commands for working with Docker.](#)
- [Description of the parameters for launching LUNA PLATFORM services and creating databases.](#)
- [Actions to enable saving LP service logs to files.](#)
- [Configuring Docker log rotation.](#)
- [Setting custom InfluxDB settings.](#)
- [Using Python Matcher service with Python Matcher Proxy service.](#)
- [System scaling.](#)
- [Compiling the VLMatch library for Oracle.](#)

## 3.1 Monitoring and logs visualization using Grafana

Monitoring visualization is performed by the LUNA Dashboards service, which contains the Grafana monitoring data visualization platform with configured LUNA PLATFORM dashboards.

If necessary, you can install customized dashboards for Grafana separately. See the “LUNA Dashboards” section in the administrator manual for more information.

Together with Grafana, you can use the Grafana Loki log aggregation system, which enables you to flexibly work with LUNA PLATFORM logs. The Promtail agent is used to deliver LUNA PLATFORM logs to Grafana Loki (for more information, see the “Grafana Loki” section in the administrator manual).

### 3.1.1 LUNA Dashboards

**Note:** To work with Grafana you need to use InfluxDB version 2.

**Note:** Before updating, make sure that the old LUNA Dashboards container is deleted.

#### 3.1.1.1 Run LUNA Dashboards container

Use the `docker run` command with these parameters to run Grafana:

```
docker run \  
--restart=always \  
--detach=true \  
--network=host \  
--name=grafana \  
-v /etc/localtime:/etc/localtime:ro \  
dockerhub.visionlabs.ru/luna/luna-dashboards:v.0.1.0
```

Use “`http://IP_ADDRESS:3000`” to go to the Grafana web interface when the LUNA Dashboards and InfluxDB containers are running.

### 3.1.2 Grafana Loki

**Note:** Grafana Loki requires LUNA Dashboards to be running.

**Note:** Before updating, make sure that the old Grafana Loki and Promtail containers are removed.

#### 3.1.2.1 Run Grafana Loki container

Use the `docker run` command with these parameters to run Grafana Loki:

```
docker run \  
--name=loki \  
--restart=always \  
--detach=true \  
--network=host \  
-v /etc/localtime:/etc/localtime:ro \  
dockerhub.visionlabs.ru/luna/loki:2.7.1
```

### 3.1.2.2 Run Promtail container

Use the `docker run` command with these parameters to run Promtail:

```
docker run \  
-v /var/lib/luna/current/example-docker/logging/promtail.yml:/etc/promtail/  
  luna.yml \  
-v /var/lib/docker/containers:/var/lib/docker/containers \  
-v /etc/localtime:/etc/localtime:ro \  
--name=promtail \  
--restart=always \  
--detach=true \  
--network=host \  
dockerhub.visionlabs.ru/luna/promtail:2.7.1 \  
-config.file=/etc/promtail/luna.yml -client.url=http://127.0.0.1:3100/loki/  
  api/v1/push -client.external-labels=job=containerlogs,pipeline_id=,job_id  
  =,version=
```

Here:

- `-v /var/lib/luna/current/example-docker/logging/promtail.yml:/etc/promtail/luna.yml` — Mounting the configuration file to the Promtail container.
- `-config.file=/etc/promtail/luna.yml` — Flag with the address of the configuration file.
- `-client.url=http://127.0.0.1:3100/loki/api/v1/push` — Flag with the address of deployed Grafana Loki.
- `-client.external-labels=job=containerlogs,pipeline_id=,job_id=,version=` — Static labels to add to all logs sent to Grafana Loki.

## 3.2 Docker commands

### 3.2.1 Show containers

To show the list of launched Docker containers use the command:

```
docker ps
```

To show all the existing Docker containers use the command:

```
docker ps -a
```

### 3.2.2 Copy files to container

You can transfer files into the container. Use the `docker cp` command to copy a file into the container.

```
docker cp <file_location> <container_name>:<folder_inside_container>
```

### 3.2.3 Enter container

You can enter individual containers using the following command:

```
docker exec -it <container_name> bash
```

To exit the container, use the command:

```
exit
```

### 3.2.4 Images names

You can see all the names of the images using the command:

```
docker images
```

### 3.2.5 Delete image

If you need to delete an image:

- Run the `docker images` command.

- Find the required image, for example `dockerhub.visionlabs.ru/luna/luna-image-store`.
- Copy the corresponding image ID from the IMAGE ID, for example, “61860d036d8c”.
- Specify it in the deletion command:

```
docker rmi -f 61860d036d8c
```

Delete all the existing images.

```
docker rmi -f $(docker images -q)
```

### 3.2.6 Stop container

You can stop the container using the command:

```
docker stop <container_name>
```

Stop all the containers:

```
docker stop $(docker ps -a -q)
```

### 3.2.7 Delete container

If you need to delete a container:

- Run the “`docker ps`” command.
- Stop the container (see [Stop container](#)).
- Find the required image, for example `dockerhub.visionlabs.ru/luna/luna-image-store`.
- Copy the corresponding container ID from the CONTAINER ID column, for example, “23f555be8f3a”.
- Specify it in the deletion command:

```
docker container rm -f 23f555be8f3a
```

Delete all the containers.

```
docker container rm -f $(docker container ls -aq)
```

#### 3.2.7.1 Check service logs

You can use the following command to show logs for the service:

```
docker logs <container_name>
```

### 3.3 Launching parameters description

When launching a Docker container for a LUNA PLATFORM service you should specify additional parameters required for the service launching.

The parameters specific for a particular container are described in the section about this container launching.

All the parameters given in the service launching example are required for proper service launching and utilization.

#### 3.3.1 Launching services parameters

Example command of launching LP services containers:

```
docker run \  
--env=CONFIGURATOR_HOST=127.0.0.1 \  
--env=CONFIGURATOR_PORT=5070 \  
--env=PORT=<Port_of_the_launched_service> \  
--env=WORKER_COUNT=1 \  
--env=RELOAD_CONFIG=1 \  
--env=RELOAD_CONFIG_INTERVAL=10 \  
-v /etc/localtime:/etc/localtime:ro \  
-v /tmp/logs/<service>:/srv/logs/ \  
--name=<service_container_name> \  
--restart=always \  
--detach=true \  
--network=host \  
dockerhub.visionlabs.ru/luna/<service-name>:<version>
```

The following parameters are used when launching LP services containers:

- `docker run` — Command for running the selected image as a new container.
- `dockerhub.visionlabs.ru/luna/<service-name>:<version>` — Sets the image required for the container launching.

Links to download the container images you need are available in the description of the corresponding container launching.

- `--network=host` — Sets that a network is not simulated and the server network is used. If you need to change the port for third-party party containers, you should change this string to `-p 5440:5432`. Where the first port 5440 is the local port and 5432 is the port used inside the container. The example is given for PostgreSQL.

- `--env=` — Sets the environment variables required to run the container (see the “[Service arguments](#)” section).
- `--name=<service_container_name>` — Sets the name of the launched container. The name must be unique. If there is a container with the same name, an error will occur.
- `--restart=always` — Sets a restart policy. The daemon will always restart the container regardless of the exit status.
- `--detach=true` — Run the container in the background mode.
- `-v` — Enables you to mount the content of a server folder into a volume in the container. Thus their contents will synchronize. The following general data is mounted:
- `/etc/localtime:/etc/localtime:ro` — Sets the current time zone used by the system in the container.
- `/tmp/logs/<service>:/srv/logs/` — Enables copying of the folder with service logs to your server `/tmp/logs/<service>` directory. You can change the directory where the logs will be saved according to your needs.

### 3.3.1.1 Service arguments

Each service in LUNA PLATFORM has its own launch arguments. These arguments can be passed through:

- Setting a flag for the launch script (`run.py`) of the corresponding service.
- Setting environment variables (`--env`) on the Docker command line.

For example, using the `--help` flag you can get a list of all available arguments. An example of passing an argument to an API service:

```
docker run --rm dockerhub.visionlabs.ru/luna/luna-api:v.6.29.0 python3 /srv/luna_api/run.py --help
```

List of main arguments:

Launch flag	Environment variable	Description
<code>--port</code>	PORT	Port on which the service will listen for connections.
<code>--workers</code>	WORKER_COUNT	Number of workers for the service.
<code>--log_suffix</code> <code>--log_suffix</code>	LOG_SUFFIX LOG_SUFFIX	Suffix added to log file names (with the option to write logs to a file enabled).

<code>--config-reload</code>	RELOAD_CONFIG	Enable automatic configuration reload. See “Automatic configurations reload” in the LUNA PLATFORM 5 administrator manual.
<code>--pulling-time</code>	RELOAD_CONFIG_INTERVAL	Configuration checking period (default 10 seconds). See “Automatic configurations reload” in the LUNA PLATFORM 5 administrator manual.
<code>--luna-config</code> <code>--luna-config</code>	CONFIGURATOR_HOST, CONFIGURATOR_PORT	Address of the Configurator service for downloading settings. For <code>--luna-config</code> it is sent in the format <code>http://localhost:5070/1</code> . For environment variables, the host and port are set explicitly. If the argument is not given, the default configuration file will be used.
<code>--config</code>	None	Path to the file with service configurations.
<code>--&lt;config_name&gt;</code>	<code>--EXTEND_CMD=&lt;config_name&gt;</code>	Tag of the specified configuration in the Configurator. When setting this configuration, the value of the tagged configuration will be used. Example: <code>--INFLUX_MONITORING TAG_1</code> <b>Note:</b> You must pre-tag the appropriate configuration in. Configurator. <b>Note:</b> Only works with the <code>--luna-config</code> flag.
<code>--tls_cert</code>	None	Path to the SSL certificate for launching the service using the HTTPS protocol.
<code>--tls_key</code>	None	Path to the SSL private key for launching the service using the HTTPS protocol.
<code>--tls_key_pass</code>	None	Password for the SSL private key for launching the service using the HTTPS protocol.

The list of arguments may vary depending on the service.

It is also possible to override the settings of services at their start using environment variables.

The `VL_SETTINGS` prefix is used to redefine the settings. Examples:

- `--env=VL_SETTINGS.INFLUX_MONITORING.SEND_DATA_FOR_MONITORING=0`. Using the environment variable from this example will set the “`SEND_DATA_FOR_MONITORING`” setting for the `INFLUX_MONITORING` section to “0”.
- `--env=VL_SETTINGS.OTHER.STORAGE_TIME=LOCAL`. For non-compound settings (settings that are located in the “OTHER” section in the configuration file), you must specify the “OTHER” prefix. Using the environment variable from this example will set the value of the “`STORAGE_TIME`” setting (if the service uses this setting) to “LOCAL”.

### Passing flags using environment variable

Flags for which an environment variable is not explicitly allocated can be passed using the environment variable `EXTEND_CMD`.

For example, you can pass the configurations tag in the following way:

```
--env=EXTEND_CMD="--INFLUX_MONITORING=TAG_1 --LUNA_EVENTS_DB=TAG_2"
```

### 3.3.2 Creating DB parameters

Example command of launching containers for database migration or database creation:

```
docker run \  
-v /etc/localtime:/etc/localtime:ro \  
-v /tmp/logs/<service>:/srv/logs/ \  
--rm \  
--network=host \  
dockerhub.visionlabs.ru/luna/<service-name>:<version> \  
python3 ./base_scripts/db_create.py --luna-config http://localhost:5070/1
```

The following parameters are used when launching containers for database migration or database creation:

Here:

- `--rm` — Sets if the container is deleted after all the specified scripts finish processing.
- `python3 ./base_scripts/db_create.py` — Sets Python version and a script `db_create.py` launched in the container. The script is used for the database structure creation.
- `--luna-config http://localhost:5070/1` — Sets where the launched script should receive configurations. By default, the service requests configurations from the Configurator service.

## 3.4 Logging to server

To enable saving logs to the server, you should:

- Create directories for logs on the server.
- Activate log recording and set the location of log storage inside LP service containers.
- Configure synchronization of log directories in the container with logs on the server using the `volume` argument at the start of each container.

### 3.4.1 Create logs directory

Below are examples of commands for creating directories for saving logs and assigning rights to them for all LUNA PLATFORM services.

```
mkdir -p /tmp/logs/configurator /tmp/logs/image-store /tmp/logs/accounts /  
tmp/logs/faces /tmp/logs/licenses /tmp/logs/events /tmp/logs/python-  
matcher /tmp/logs/handlers /tmp/logs/remote-sdk /tmp/logs/tasks /tmp/logs  
/tasks-worker /tmp/logs/sender /tmp/logs/api /tmp/logs/admin /tmp/logs/  
backport3 /tmp/logs/backport4
```

```
chown -R 1001:0 /tmp/logs/configurator /tmp/logs/image-store /tmp/logs/  
accounts /tmp/logs/faces /tmp/logs/licenses /tmp/logs/events /tmp/logs/  
python-matcher /tmp/logs/handlers /tmp/logs/remote-sdk /tmp/logs/tasks /  
tmp/logs/tasks-worker /tmp/logs/sender /tmp/logs/api /tmp/logs/admin /tmp  
/logs/backport3 /tmp/logs/backport4
```

If you need to use the Python Matcher Proxy service, then you need to additionally create the `/tmp/logs/python-matcher-proxy` directory and set its permissions.

### 3.4.2 Logging activation

#### 3.4.2.1 LP services logging activation

To enable logging to file, you need to set the `log_to_file` and `folder_with_logs` settings in the `<SERVICE_NAME>_LOGGER` section of the settings for each service.

#### **Automatic method (before/after starting Configurator)**

To update logging settings, you can use the `logging.json` settings file provided with the distribution package.

Run the following command after starting the Configurator service:

```
docker cp /var/lib/luna/current/extras/conf/logging.json luna-configurator:/
srv/luna_configurator/used_dumps/logging.json
```

Update your logging settings with the copied file.

```
docker exec -it luna-configurator python3 ./base_scripts/db_create.py --dump
-file /srv/luna_configurator/used_dumps/logging.json
```

### Manual method (after starting Configurator)

Go to the Configurator service interface (127.0.0.1:5070) and set the logs path in the container in the `folder_with_logs` parameter for all services whose logs need to be saved. For example, you can use the path `/srv/logs`.

Set the `log_to_file` option to `true` to enable logging to a file.

#### 3.4.2.2 Configurator service logging activation (before/after Configurator start)

The Configurator service settings are not located in the Configurator user interface, they are located in the following file:

```
/var/lib/luna/current/example-docker/luna_configurator/configs/
luna_configurator_postgres.conf
```

You should change the logging parameters in this file before starting the Configurator service or restart it after making changes.

Set the path to the logs location in the container in the `FOLDER_WITH_LOGS = ./` parameter of the file. For example, `FOLDER_WITH_LOGS = /srv/logs`.

Set the `log_to_file` option to `true` to enable logging to a file.

#### 3.4.3 Mounting directories with logs when starting services

The log directory is mounted with the following argument when starting the container:

```
-v <server_logs_folder>:<container_logs_folder> \
```

where `<server_logs_folder>` is the directory created in the [create logs directory](#) step, and `<container_logs_folder>` is the directory created in the [activate logging](#) step.

Example of command to launch the API service with mounting a directory with logs:

```
docker run \  
--env=CONFIGURATOR_HOST=127.0.0.1 \  
--env=CONFIGURATOR_PORT=5070 \  
--env=PORT=5000 \  
--env=WORKER_COUNT=1 \  
--env=RELOAD_CONFIG=1 \  
--env=RELOAD_CONFIG_INTERVAL=10 \  
--name=luna-api \  
--restart=always \  
--detach=true \  
-v /etc/localtime:/etc/localtime:ro \  
-v /tmp/logs/api:/srv/logs \  
--network=host \  
dockerhub.visionlabs.ru/luna/luna-api:v.6.29.0
```

The example container launch commands in this documentation contain these arguments.

### 3.5 Docker log rotation

To limit the size of logs generated by Docker, you can set up automatic log rotation. To do this, add the following data to the `/etc/docker/daemon.json` file:

```
{
  "log-driver": "json-file",
  "log-opts": {
    "max-size": "100m",
    "max-file": "5"
  }
}
```

This will allow Docker to store up to 5 log files per container, with each file being limited to 100MB.

After changing the file, you need to restart Docker:

```
systemctl reload docker
```

The above changes are the default for any newly created container, they do not apply to already created containers.

### 3.6 Set custom InfluxDB settings

If you are going to use InfluxDB OSS 2, then you need to update the monitoring settings in Configurator service.

There are the following settings for InfluxDB OSS 2:

```
"send_data_for_monitoring": 1,
"use_ssl": 0,
"flushing_period": 1,
"host": "127.0.0.1",
"port": 8086,
"organization": "<ORGANIZATION_NAME>",
"token": "<TOKEN>",
"bucket": "<BUCKET_NAME>",
"version": <DB_VERSION>
```

You can update InfluxDB settings in the Configurator service by following these steps:

- Open the following file:

```
vi /var/lib/luna/current/extras/conf/influx2.json
```

- Set required data.
- Save changes.
- Copy the file to the influxDB container:

```
docker cp /var/lib/luna/current/extras/conf/influx2.json luna-configurator:/srv/
```

- Update settings in the Configurator.

```
docker exec -it luna-configurator python3 ./base_scripts/db_create.py --dump
-file /srv/influx2.json
```

You can also manually update settings in the Configurator service user interface.

The Configurator service configurations are set separately.

- Open the file with the Configurator configurations:

```
vi /var/lib/luna/current/example-docker/luna_configurator/configs/
luna_configurator_postgres.conf
```

- Set required data.
- Save changes.
- Restart Configurator:

```
docker restart luna-configurator
```

### 3.7 Use Python Matcher with Python Matcher Proxy

As mentioned earlier, along with the Python Matcher service, you can additionally use the Python Matcher Proxy service, which will redirect matching requests either to the Python Matcher service or to the matching plugins. Plugins may significantly improve matching processing performance. For example, it is possible to organize the storage of the data required for matching operations and additional objects fields in separate storage using plugins, which will speed up access to the data compared to the use of the standard LUNA PLATFORM database.

To use the Python Matcher service with Python Matcher Proxy, you should additionally launch the appropriate container, and then set a certain setting in the Configurator service. Follow the steps below only if you are going to use matching plugins.

See the description and usage of matching plugins in the administrator manual.

#### 3.7.1 Python Matcher proxy container launch

Use the following command to launch the service:

After starting the container, you need to set the "luna\_matcher\_proxy":true parameter in the "ADDITIONAL\_SERVICES\_USAGE" section in the Configurator service.

```
docker run \  
--env=CONFIGURATOR_HOST=127.0.0.1 \  
--env=CONFIGURATOR_PORT=5070 \  
--env=PORT=5110 \  
--env=WORKER_COUNT=1 \  
--env=RELOAD_CONFIG=1 \  
--env=RELOAD_CONFIG_INTERVAL=10 \  
--env=SERVICE_TYPE="proxy" \  
-v /etc/localtime:/etc/localtime:ro \  
-v /tmp/logs/python-matcher-proxy:/srv/logs \  
--name=luna-python-matcher-proxy \  
--restart=always \  
--detach=true \  
--network=host \  
dockerhub.visionlabs.ru/luna/luna-python-matcher:v.1.9.9
```

After launching the container, you need to set the following value in the Configurator service.

```
ADDITIONAL_SERVICES_USAGE = "luna_matcher_proxy":true
```

### 3.8 System scaling

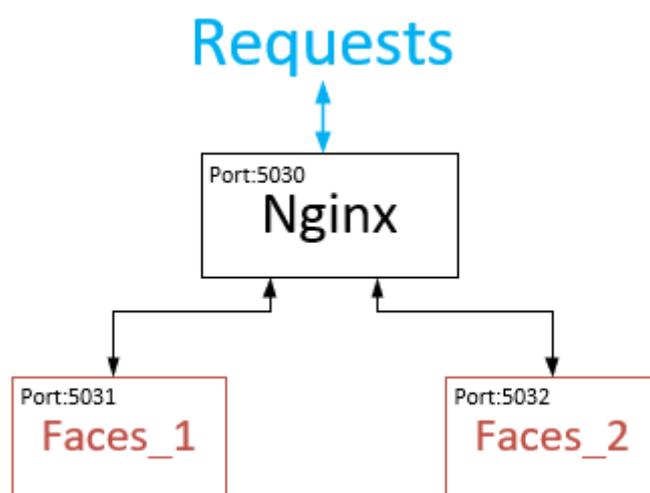

All LP services are linearly scalable and can be located on several services.

You can run additional containers with LP services to improve performance and fail-safety. The number of services and the characteristics of servers depend on your tasks.

To increase performance, you may either improve the performance of a single server or increase the number of servers used by distributing most resource-intensive components of the system.

Balancers are used for the distribution of requests among the launched service instances. This approach provides the necessary processing speed and the required fail-safety level for specific customer's tasks. In the case of a node failure, the system will not stop: requests will be redirected to another node.

The image below shows two instances of the Faces service balanced by Nginx. Nginx receives requests on port 5030 and routes them to Faces instances. The faces services are launched on ports 5031 and 5032.

**Figure 1:** Faces service balancing

It is strongly recommended to regularly back up databases to a separate server regardless of the fail-safety level of the system. It allows you not to lose data in case of unforeseen circumstances.

MQs, databases, and balancers used by LUNA PLATFORM are products of third-party developers. You should configure them according to the recommendations of the corresponding vendors.

The Remote SDK service and the Python Matcher service perform the most resource-intensive operations.

**The Remote SDK service** performs mathematical image transformations and descriptors extraction. The operations require significant computational resources. Both CPU and GPU can be used for computations.

GPU usage is preferable since it improves the processing of requests. However, not all types of video cards are supported.

**The Python Matcher service** performs matching with lists. Matching requires CPU resources, however, you also should allocate as much RAM as possible for each Python Matcher instance. The RAM is used to store descriptors received from a database. Thus matcher does not require to request each descriptor from the database.

When distributing instances on several servers, you should consider the performance of each server. For example, if a large task is executed by several Python Matcher instances, and one of the instances is on the server with low performance, this can slow down the execution of the entire task.

For each instance of the service, you can set the number of workers. The greater the number of workers, the more resources and memory are consumed by the service instance. See the detailed information in the “Worker processes” section of the LUNA PLATFORM administrator manual.

### 3.8.1 Launching several containers

There are two steps required for launching several instances of the same LP service

1. Run several containers of the service.

You must launch the required number of service by using the corresponding command for the service.

For example, for the API service you must run the following command with updated parameters.

```
docker run \  
--env=CONFIGURATOR_HOST=127.0.0.1 \  
--env=CONFIGURATOR_PORT=5070 \  
--env=PORT=<port> \  
-v /etc/localtime:/etc/localtime:ro \  
-v /tmp/logs/<folder_name>:/srv/logs \  
--name=<name> \  
--restart=always \  
--detach=true \  
--network=host \  
dockerhub.visionlabs.ru/luna/luna-api:v.6.29.0
```

When running several similar containers the following parameters of the containers must differ:

- `--env=PORT=<port>` — Specified port for similar containers must differ. You must specify an available port for the instance. For example, “5001”, “5002”. The “5000” port will be specified for the Nginx balancer.
- `/tmp/logs/<folder_name>:/srv/logs` — Specified folder name for logs must differ to distinguish logs for different service instances.

- `--name=<container_name>` — Name of the launched container must differ as it is prohibited to launch two containers with the same name. For example, “api\_1”, “api\_2”.
- `--gpus device=0` — CORE services usually utilize different GPU devices. Thus you should specify different device numbers.

2. Configure your balancer (e.g., Nginx) for routing requests to the services.

For each scaled LP service, you must set a port where Nginx will listen to service requests and real ports of each service instance where Nginx will redirect the requests.

An example of Nginx configuration file can be found here:

“`/var/lib/luna/current/extras/conf/nginx.conf`”.

You can use another balancer, but its utilization is not described in this documentation.

### 3.9 VLMatch for Oracle

**Note:** The following instruction describes installation for Oracle 21c.

You can find all the required files for the VLMatch user-defined extension (UDx) compilation in the following directory:

```
/var/lib/luna/current/extras/VLMatch/oracle
```

For VLMatch UDx function compilation one needs to:

- Install required environment, see [requirements](#):

```
sudo yum install gcc g++
```

- Change SDK\_HOME variable — oracle sdk root (default is \$ORACLE\_HOME/bin, check \$ORACLE\_HOME environment variable is set) in the makefile:

```
vi /var/lib/luna/current/extras/VLMatch/oracle/make.sh
```

- Open the directory and run the file “make.sh”.

```
cd /var/lib/luna/current/extras/VLMatch/oracle
```

```
chmod +x make.sh
```

```
./make.sh
```

- Define the library and the function inside the database (from database console):

```
CREATE OR REPLACE LIBRARY VLMatchSource AS '$ORACLE_HOME/bin/VLMatchSource.so';
CREATE OR REPLACE FUNCTION VLMatch(descriptorFst IN RAW, descriptorSnd IN
  RAW, length IN BINARY_INTEGER)
  RETURN BINARY_FLOAT
AS
  LANGUAGE C
  LIBRARY VLMatchSource
  NAME "VLMatch"
  PARAMETERS (descriptorFst BY REFERENCE, descriptorSnd BY REFERENCE,
    length UNSIGNED SHORT, RETURN FLOAT);
```

- Test function within call (from database console):

```
SELECT VLMatch(HEXTORAW('
1234567890123456789012345678901234567890123456789012345678901234'),
HEXTORAW('
0123456789012345678901234567890123456789012345678901234567890123'), 32)
FROM DUAL;
```

The result returned by the database must be “0.4765625”.
